- When a function calls itself, this is known as recursion.
- This is an important theme in Computer Science that crops up time & time again.
- Can sometimes lead to very simple and elegant programs.
- Let's look at some toy examples to begin with.

```
#include <stdio.h>
     #include <string.h>
     #define SWAP(A,B) {char temp; temp=A;A=B;B=temp;}
     void strrev(char* s, int n);
     int main (void)
        char str[] = "Hello World!":
        strrev(str. strlen(str)):
12
        printf("%s\n", str);
        return 0:
14
15
     /* Iterative Inplace String Reverse */
17
     void strrev(char* s. int n)
18
19
        for(int i=0, j=n-1; i<j; i++, j--){
            SWAP(s[i], s[j]);
20
21
22
```

Execution:

!dlroW olleH

Recursion for *strrev()*

```
#include <stdio.h>
    #include <string.h>
    #define SWAP(A,B) {char temp; temp=A;A=B;B=temp;}
    void strrev(char* s, int start, int end);
    int main(void)
       char str[] = "Hello World!";
        strrev(str. 0. strlen(str)-1):
        printf("%s\n", str);
13
14
       return 0;
15
    /* Recursive : Inplace String Reverse */
    void strrev(char* s. int start, int end)
19
       if(start >= end){
           return:
       SWAP(s[start], s[end]);
23
24
        strrev(s. start+1, end-1);
```

Execution:

!dlroW olleH

Recursion for *strrev()*

```
#include <stdio.h>
    #include <string.h>
    #define SWAP(A,B) {char temp; temp=A;A=B;B=temp;}
    void strrev(char* s, int start, int end);
    int main(void)
       char str[] = "Hello World!";
       strrev(str. 0. strlen(str)-1):
       printf("%s\n", str);
13
14
       return 0:
15
    /* Recursive : Inplace String Reverse */
    void strrev(char* s, int start, int end)
19
       if(start >= end){
20
           return:
       SWAP(s[start], s[end]);
23
24
       strrev(s. start+1, end-1);
```

• We need to change the function prototype.

Execution:

!dlroW olleH

Recursion for *strrev()*

```
#include <stdio.h>
    #include <string.h>
    #define SWAP(A.B) {char temp: temp=A:A=B:B=temp:}
    void strrev(char* s, int start, int end);
    int main(void)
       char str[] = "Hello World!";
       strrev(str. 0. strlen(str)-1):
       printf("%s\n", str);
13
14
       return 0:
15
    /* Recursive : Inplace String Reverse */
    void strrev(char* s, int start, int end)
19
       if(start >= end){
20
           return:
       SWAP(s[start], s[end]);
23
24
       strrev(s. start+1, end-1):
```

- We need to change the function prototype.
- This allows us to track both the start and the end of the string.

Execution:

IdlroW olleH

The Fibonacci Sequence

A well known example of a recursive function is the Fibonacci sequence. The first term is 1, the second term is 1 and each successive term is defined to be the sum of the two previous terms, i.e. :

```
fib(1) is 1
fib(2) is 1
fib(n) is fib(n-1)+fib(n-2)
```

1,1,2,3,5,8,13,21, ...

N: Recursion 5/8'

```
#include <stdio.h>
    #define MAXFIB 24
    int fibonacci(int n);
     int main(void)
        for(int i=1: i <= MAXFIB: i++){
           printf("%d = %d\n", i, fibonacci(i));
13
14
15
        return 0;
16
17
     int fibonacci(int n)
19
        if(n \le 2)
           return 1;
       int b = 1:
        int next:
        for (int i=3; i \le n; i++){
           next = a + b:
           a = b:
           b = next:
        return b:
32
```

```
#include <stdio.h>
    #define MAXFIB 24
    int fibonacci(int n):
     int main(void)
        for(int i=1: i <= MAXFIB: i++){</pre>
            printf("%d = %d\n", i, fibonacci(i)):
13
14
15
        return 0;
16
17
     int fibonacci(int n)
19
20
        if(n \le 2)
           return 1;
        int b = 1:
        int next:
        for (int i=3; i \le n; i++){
           next = a + b:
           a = b:
29
           b = next:
30
31
        return b:
32
```

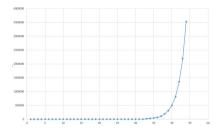

Execution:

```
1 = 1
 = 13
 = 21
9 = 34
10 = 55
11 = 89
12 = 144
13 = 233
14 = 377
15 = 610
16 = 987
17 = 1597
18 = 2584
19 = 4181
20 = 6765
21 = 10946
22 = 17711
23 = 28657
24 = 46368
```

```
#include <stdio.h>
#define MAXFIB 24
int fibonacci(int n);
int main(void)
   for(int i=1; i <= MAXFIB; i++){</pre>
      printf("%d = %d\n", i, fibonacci(i));
   return 0;
int fibonacci(int n)
   if (n == 1) return 1:
   if (n == 2) return 1:
   return ( fibonacci(n-1)+fibonacci(n-2));
```

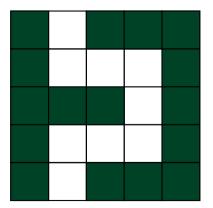

```
#include <stdio.h>
    #define MAXFIB 24
    int fibonacci(int n);
     int main(void)
        for(int i=1; i <= MAXFIB; i++){</pre>
           printf("%d = %d\n", i, fibonacci(i));
       return 0;
    int fibonacci(int n)
20
21
       if (n == 1) return 1:
       if (n == 2) return 1:
        return ( fibonacci(n-1)+fibonacci(n-2));
```

It's interesting to see how run-time increases as the length of the sequence is raised.

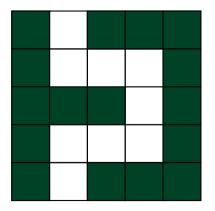

Maze Escape

The correct route through a maze can be obtained via recursive, rather than iterative, methods.

Maze Escape

The correct route through a maze can be obtained via recursive, rather than iterative, methods.

```
bool explore(int x, int y, char mz[YS][XS])
  if mz[y][x] is exit return true;
  Mark mz[y][x] so we don't return here
  if we can go up:
    if(explore(x, y+1, mz)) return true
  if we can go right:
    if(explore(x+1, y, mz)) return true
  Do left & down in a similar manner
  return false: // Failed to find route
```

 Here we consider the ways to permute a string (or more generally an array)

- In binary searching, we simply used the middle of an ordered list as a best guess as to where to begin the search.
- Now we use an interpolation involving the key, the start of the list and the end.

$$i = (k - I[0])/(I[n-1] - I[0]) * n$$

• when searching for '15':

```
0 4 5 9 10 12 15 20
```

```
int interp(int k. const int* a. int l. int r)
   int m:
   double md:
   while(1 \le r)
      md = ((double)(k-a[1])/
            (double)(a[r]-a[1])*
            (double)(r-1)
           +(double)(1):
      m = 0.5 + md:
      if((m > r) | | (m < 1)){
         return -1:
      if (k == a[m])
         return m:
         if (k > a[m]) {
            1 = m + 1:
         elsef
            r = m-1:
```

 fast to delete an element.

Task	Fixed Array	Realloc Array	Linked List
Insert new element	O(1) at end	O(1) at end	O(1) at front
	if space	but realloc()	
Search for an element	O(n)	O(n)	O(n)
	brute force	brute force	brute force
Search + delete	O(n) + O(n)	O(n) + O(n)	O(n) + O(1)
	move left	move left	delete 'free'

 If we had ordered our ADT (ie. the elements were sorted), then the searches could be via a binary / interpolation search, leading to O(log n) or O(log log n) search times.

ADTs Making Coding Simpler

Linked List code from the previous Chapter:

```
#include <stdio.h>
    #include <stdlib.h>

Binary Search Trees

In a binary search tree the left-hand tree of a parent contains all keys less than the parent node, and the right-hand side all the keys greater than the parent node.

Binary Search Trees

In a binary search tree the left-hand tree of a parent contains all keys less than the parent node, and the right-hand side all the keys greater than the parent node.

Counting from cell 1, for a tree with *n* nodes:

To find	Use	Iff
The root	A[1]	A is nonempty
The left child of $A[i]$	A[2i]	$2i \leq n$
The parent of $A[i]$	A[i/2]	i > 1
Is A[i] a leaf?	True	2 <i>i</i> > <i>n</i>

        putchar(' ');
        queue_enqueue(q, _leftchild((int)n));
        queue_enqueue(q, _rightchild((int)n));
}
```

Binary Search Trees : Complexity

ullet So, in a nicely balanced tree, insertion, deletion and search are all $O(\log n)$.

Binary Search Trees: Complexity

- So, in a nicely balanced tree, insertion, deletion and search are all $O(\log n)$.
- But: if the root of the tree is not well chosen, or the keys to be inserted are ordered, the tree can become a linked list!

Binary Search Trees: Complexity

- So, in a nicely balanced tree, insertion, deletion and search are all $O(\log n)$.
- But: if the root of the tree is not well chosen, or the keys to be inserted are ordered, the tree can become a linked list!

• In this case, complexity becomes O(n).

Binary Search Trees : Complexity

- So, in a nicely balanced tree, insertion, deletion and search are all $O(\log n)$.
- But: if the root of the tree is not well chosen, or the keys to be inserted are ordered, the tree can become a linked list!
- In this case, complexity becomes O(n).
- The tree search performs best when well balanced trees are formed.

Binary Search Trees: Complexity

- So, in a nicely balanced tree, insertion, deletion and search are all $O(\log n)$.
- But: if the root of the tree is not well chosen, or the keys to be inserted are ordered, the tree can become a linked list!
- In this case, complexity becomes O(n).
- The tree search performs best when well balanced trees are formed.
- Large body of literature about creating & re-balancing trees Red-Black trees, Tries, 2-3 trees, AVL trees etc.

 Often we wish to compress data, to reduce storage requirements, or to speed transmission.

- Often we wish to compress data, to reduce storage requirements, or to speed transmission.
- Text is particularly suited to compression since using one byte per character is wasteful - some letters occur much more frequently.

- Often we wish to compress data, to reduce storage requirements, or to speed transmission.
- Text is particularly suited to compression since using one byte per character is wasteful - some letters occur much more frequently.
- Need to give frequently occurring letters short codes, typically a few bits. Less common letters can have long bit patterns.

ADTs: Hashing

 To keep records of employees we might index (search) them by using their National Insurance number:

xx-##-##-##-x

ADTs: Hashing

 To keep records of employees we might index (search) them by using their National Insurance number:

```
xx-##-##-##-x
```

• There are 17.6 billion combinations (around 2³⁴).

ADTs : Hashing

 To keep records of employees we might index (search) them by using their National Insurance number:

```
xx-##-##-##-x
```

- There are 17.6 billion combinations (around 2³⁴).
- Could use an array of 17.6 billion entries, which would make searching for a particular entry trivial!

ADTs: Hashing

 To keep records of employees we might index (search) them by using their National Insurance number:

xx-##-##-##-x

- There are 17.6 billion combinations (around 2³⁴).
- Could use an array of 17.6 billion entries, which would make searching for a particular entry trivial!
- Especially wasteful since only our (5000) employees need to be stored.

 To keep records of employees we might index (search) them by using their National Insurance number:

xx-##-##-##-x

- There are 17.6 billion combinations (around 2³⁴).
- Could use an array of 17.6 billion entries, which would make searching for a particular entry trivial!
- Especially wasteful since only our (5000) employees need to be stored.

 To keep records of employees we might index (search) them by using their National Insurance number:

- There are 17.6 billion combinations (around 2³⁴).
- Could use an array of 17.6 billion entries, which would make searching for a particular entry trivial!
- Especially wasteful since only our (5000) employees need to be stored.

 Here we examine a method that, using an array of 6000 elements, would require 2.1 comparisons on average.

- A hash function is a mapping, h(K), that maps from key K, onto the index of an entry.
- A black-box into which we insert a key (e.g. NI number) and out pops an array index.
- As an example lets use an array of size 11 to store some airport codes, e.g. PEK, BRS, FRA.

In a three letter string X₂X₁X₀ the letter 'A' has the value 0,
 'B' has the value 1 etc.

- In a three letter string X₂X₁X₀ the letter 'A' has the value 0,
 'B' has the value 1 etc.
- One hash function is:

$$h(K) = (X_2 * 26^2 + X_1 * 26 + X_0)\%11$$

- In a three letter string X₂X₁X₀ the letter 'A' has the value 0, 'B' has the value 1 etc.
- One hash function is:

$$h(K) = (X_2 * 26^2 + X_1 * 26 + X_0)\%11$$

• Applying this to "DCA": h("DCA") = $(3*26^2 + 2*26 + 0)\%11$ h("DCA") = (2080)%11h("DCA") = 1

- In a three letter string X₂X₁X₀ the letter 'A' has the value 0, 'B' has the value 1 etc.
- One hash function is:

$$h(K) = (X_2 * 26^2 + X_1 * 26 + X_0)\%11$$

• Applying this to "DCA": h("DCA") = $(3*26^2 + 2*26 + 0)\%11$ h("DCA") = (2080)%11h("DCA") = 1

- In a three letter string X₂X₁X₀ the letter 'A' has the value 0,
 'B' has the value 1 etc.
- One hash function is:

$$h(K) = (X_2 * 26^2 + X_1 * 26 + X_0)\%11$$

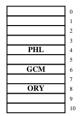

• Applying this to "DCA": h("DCA") = $(3*26^2 + 2*26 + 0)\%11$ h("DCA") = (2080)%11h("DCA") = 1 Inserting "PHL", "ORY" and "GCM":

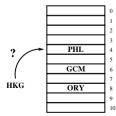

- In a three letter string X₂X₁X₀ the letter 'A' has the value 0,
 'B' has the value 1 etc.
- One hash function is:

$$h(K) = (X_2 * 26^2 + X_1 * 26 + X_0)\%11$$

• Applying this to "DCA": h("DCA") = $(3*26^2 + 2*26 + 0)\%11$ h("DCA") = (2080)%11h("DCA") = 1 • Inserting "PHL", "ORY" and "GCM":

• However, inserting "HKG" causes a collision.

 An ideal hashing function maps keys into the array in a *uniform* and *random* manner.

- An ideal hashing function maps keys into the array in a uniform and random manner.
- Collisions occur when a hash function maps two different keys onto the same address.

- An ideal hashing function maps keys into the array in a uniform and random manner.
- Collisions occur when a hash function maps two different keys onto the same address.
- It's very difficult to choose 'good' hashing functions.

- An ideal hashing function maps keys into the array in a *uniform* and *random* manner.
- Collisions occur when a hash function maps two different keys onto the same address.
- It's very difficult to choose 'good' hashing functions.
- Collisions are common the von Mises paradox. When 23 keys are randomly mapped onto 365 addresses there is a 50% chance of a collision.

- An ideal hashing function maps keys into the array in a *uniform* and *random* manner.

- If a collision occurs then keep stepping backwards (with wrap-around) until a free location is encountered.

 This simple method of open-addressing is linear-probing.

- This simple method of open-addressing is linear-probing.
- The step taken each time (probe decrement) need not be 1.

- This simple method of open-addressing is linear-probing.
- The step taken each time (probe decrement) need not be 1.
- Open-addressing through use of linear-probing is a very simple technique, double-hashing is generally much more successful.

- This simple method of open-addressing is linear-probing.
- The step taken each time (probe decrement) need not be 1.
- Open-addressing through use of linear-probing is a very simple technique, double-hashing is generally much more successful.
- A second function p(K) decides the size of the probe decrement.

- This simple method of open-addressing is linear-probing.
- The step taken each time (probe decrement) need not be 1.
- Open-addressing through use of linear-probing is a very simple technique, double-hashing is generally much more successful.
- A second function p(K) decides the size of the probe decrement.

- This simple method of open-addressing is linear-probing.
- The step taken each time (probe decrement) need not be 1.
- Open-addressing through use of linear-probing is a very simple technique, double-hashing is generally much more successful.
- A second function p(K) decides the size of the probe decrement

 The function is chosen so that two keys which collide at the same address will have different probe decrements, e.g.:

$$p(K) = MAX(1, ((X_2 * 26^2 + X_1 * 26 + X_0)/11)\%11)$$

- This simple method of open-addressing is linear-probing.
- The step taken each time (probe decrement) need not be 1.
- Open-addressing through use of linear-probing is a very simple technique, double-hashing is generally much more successful.
- A second function p(K) decides the size of the probe decrement

 The function is chosen so that two keys which collide at the same address will have different probe decrements, e.g.:

$$p(K) = MAX(1, ((X_2 * 26^2 + X_1 * 26 + X_0)/11)\%11)$$

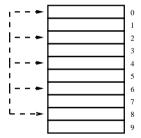

• Although "PHL" and "HKG" share the same primary hash value of h(K) = 4, they have different probe decrements:

$$p("PHL") = 4$$
$$p("HKG") = 3$$

• If the size of our array, M, was even and the probe decrement was chosen to be 2, then only half of the locations could be probed.

 If the size of our array, M, was even and the probe decrement was chosen to be 2, then only half of the locations could be probed.

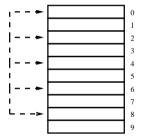

• Often we choose our table size to be a prime number and our probe decrement to be a number in the range $1 \dots M - 1$.

 If the size of our array, M, was even and the probe decrement was chosen to be 2, then only half of the locations could be probed.

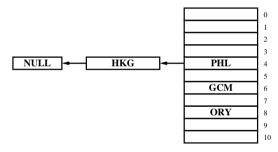

• Often we choose our table size to be a prime number and our probe decrement to be a number in the range $1 \dots M - 1$.

 If the size of our array, M, was even and the probe decrement was chosen to be 2, then only half of the locations could be probed.

• Often we choose our table size to be a prime number and our probe decrement to be a number in the range $1 \dots M - 1$.

Open-addressing is not the only method of collision reduction. Another common one is separate chaining.

A Practical Hash Function

```
#include <stdio.h>
    int hash(unsigned int sz, char *s);
    int main(void)
       char str[] = "Hello World!";
       // Hash modulus 7919
        printf("%d\n", hash(7919, str));
        return 0:
12
13
14
15
    Modified Bernstein hashing
    5381 & 33 are magic numbers required by the algorithm
19
    int hash(unsigned int sz, char *s)
       unsigned long hash = 5381;
       int c;
       while ((c = (*s++))){
           hash = 33 * hash ^ c:
        return (int)(hash%sz);
```

Execution:

5479

A Practical Hash Function

```
#include <stdio h>
    int hash(unsigned int sz. char *s):
     int main (woid)
       char str[] = "Hello World!";
       // Hash modulus 7919
        printf("%d\n", hash(7919, str));
        return 0:
12
13
15
    Modified Bernstein hashing
17
    5381 & 33 are magic numbers required by the algorithm
19
    int hash(unsigned int sz. char *s)
20
21
        unsigned long hash = 5381;
        int c:
        while ((c = (*s++))){
           hash = 33 * hash ^ c:
        return (int)(hash%sz);
```

Execution:

5479

Has similarities to the implementation of rand():

```
int rand r(unsigned int* seed):
int main (void)
  unsigned int seed = 0:
   printf("%d\n", rand r(&seed)):
  return 0:
/* This algorithm is mentioned in the ISO C standard,
   here extended for 32 bits. */
int rand_r(unsigned int* seed)
 unsigned int next = *seed;
  int result:
 next *= 1103515245;
  next += 12345:
 result = (unsigned int) (next / 65536) % 2048;
 next *= 1103515245;
 next += 12345;
 result <<= 10:
 result ^= (unsigned int) (next / 65536) % 1024:
  next *= 1103515245:
 next += 12345:
 result <<= 10:
 result ^= (unsigned int) (next / 65536) % 1024:
 *seed = next;
 return result:
```

Execution:

Cuckoo Hashing

 We have two tables, each with their own hash function.

```
Empty: copied farandoles into table 0(4)
Empty: copied bronzine into table 0(12)
Empty: copied auscultatory into table 0(5)
Empty: copied bifer into table 0(13)
Empty: copied steepgrass into table 0(6)
Empty: copied prevised into table 0(7)
Empty: copied oomph into table 0(8)
empodium, so cuckooed out auscultatory from table 0(5)
Empty: copied auscultatory into table 1(10)
interquarreled, so cuckooed out bronzine from table 0(12)
Empty: copied bronzine into table 1(5)
ranseur, so cuckooed out empodium from table 0(5)

- Quicksort can go badly wrong if the pivot key chosen is either the maximum or minimum value in the array.
- Quicksort is so loved by programmers that a library version of it exists in ANSI C.
- If you need an off-the-shelf sort, this is often a good option.

```
#include <stdio.h>
     #include <stdlib.h>
     int intcompare(const void *a, const void *b);
     int main(void)
        int a[10]:
        for (int i=0; i<10; i++){
           a[i] = 9 - i:
        gsort(a, 10, sizeof(int), intcompare):
16
        for (int i=0; i<10; i++){
           printf(" %d".a[i]):
        printf("\n"):
        return 0:
21
23
     int intcompare(const void *a, const void *b)
25
         const int *ia = (const int *)a:
         const int *ib = (const int *)b:
         return *ia - *ib:
```

 The radix sort is also know as the bin sort, a name derived from its origin as a technique used on (now obsolete) card sorters.

- The radix sort is also know as the bin sort, a name derived from its origin as a technique used on (now obsolete) card sorters.
- For integer data, repeated passes of radix sort focus on the right digit (the units), then the second digit (the tens) and so on.

- The radix sort is also know as the bin sort, a name derived from its origin as a technique used on (now obsolete) card sorters.
- For integer data, repeated passes of radix sort focus on the right digit (the units), then the second digit (the tens) and so on.
- Strings could be sorted in a similar manner.

where P is a big prime number.

• This can be expanded by Horner's method to:

Rabin-Karp II

 For a large search string, overflow can occur. We therefore move the mod operation inside the brackets:

$$(((((((13 \times 26) + 4)\%P \times 26) + 8)\%P \times 26) + 11)\%P \times 26 + 11)\%P$$

Rabin-Karp II

 For a large search string, overflow can occur. We therefore move the mod operation inside the brackets:

$$(((((((13 \times 26) + 4)\%P \times 26) + 8)\%P \times 26) + 11)\%P \times 26 + 11)\%P$$

 We can compute a hash number for the search string, and for the initial part of the master string.

Rabin-Karp II

 For a large search string, overflow can occur. We therefore move the mod operation inside the brackets:

$$(((((((13 \times 26) + 4)\%P \times 26) + 8)\%P \times 26) + 11)\%P \times 26 + 11)\%P$$

- We can compute a hash number for the search string, and for the initial part of the master string.
- When we compute the hash number for the next part of the master, most of the computation is common, we just need to take out the effect of the first letter and add in the effect of the new one.

$$(((((((13 \times 26) + 4)\%P \times 26) + 8)\%P \times 26) + 11)\%P \times 26 + 11)\%P$$

- We can compute a hash number for the search string, and for the initial part of the master string.
- When we compute the hash number for the next part of the master, most of the computation is common, we just need to take out the effect of the first letter and add in the effect of the new one.
- One small calculation each time we move one place right in the master.

$$(((((((13 \times 26) + 4)\%P \times 26) + 8)\%P \times 26) + 11)\%P \times 26 + 11)\%P$$

- We can compute a hash number for the search string, and for the initial part of the master string.
- When we compute the hash number for the next part of the master, most of the computation is common, we just need to take out the effect of the first letter and add in the effect of the new one.
- One small calculation each time we move one place right in the master.
- Complexity O(m+n) roughly, but need to check that two identical hash numbers really has identified two identical strings.

$$(((((((13 \times 26) + 4)\%P \times 26) + 8)\%P \times 26) + 11)\%P \times 26 + 11)\%P$$

31
           if(i>n-m) return n:
32
        return i:
```

The Boyer-Moore algorithm uses (in part) an array flagging which characters form part of the search string and an array telling us how far to slide right if that character appears in the master and causes a mismatch.

Execution:

```
A STRING SEARCHING EXAMPLE CONSISTING OF ...

STING

STING

STING
```

The Boyer-Moore algorithm uses (in part) an array flagging which characters form part of the search string and an array telling us how far to slide right if that character appears in the master and causes a mismatch.

Execution:

 With a right-to-left walk through the search string we see that the G and the R mismatch on the first comparison.

The Boyer-Moore algorithm uses (in part) an array flagging which characters form part of the search string and an array telling us how far to slide right if that character appears in the master and causes a mismatch.

Execution:

- With a right-to-left walk through the search string we see that the G and the R mismatch on the first comparison.
- Since R doesn't appear in the search string, we can take 5 steps to the right.

The Boyer-Moore algorithm uses (in part) an array flagging which characters form part of the search string and an array telling us how far to slide right if that character appears in the master and causes a mismatch.

Execution:

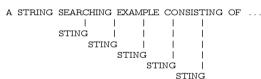

```
A STRING SEARCHING EXAMPLE CONSISTING OF ...

| | |
STING |
STING
```

- With a right-to-left walk through the search string we see that the G and the R mismatch on the first comparison.
- Since R doesn't appear in the search string, we can take 5 steps to the right.
- The next comparison is between the G and the S. We can slide the search string right until it matches the S in the master.

Boyer-Moore II

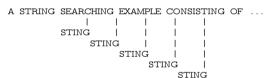

Execution:

 Now the C doesn't appear in the master and once again we can slide a full 5 places to the right.

Boyer-Moore II

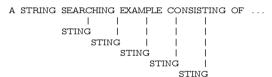

Execution:

- Now the C doesn't appear in the master and once again we can slide a full 5 places to the right.
- After 3 more full slides right we arrive at the T in CONSISTING.

Boyer-Moore II

Execution:

- Now the C doesn't appear in the master and once again we can slide a full 5 places to the right.
- After 3 more full slides right we arrive at the T in CONSISTING.
- We align the T's, and have found our match using 7 compares (plus 5 to verify the match).
